

Incomplete Cholesky factorization

In numerical analysis, an **incomplete Cholesky factorization** of a symmetric positive definite matrix is a sparse approximation of the Cholesky factorization. An incomplete Cholesky factorization is often used as a preconditioner for algorithms like the conjugate gradient method.

The Cholesky factorization of a positive definite matrix A is $A = LL^*$ where L is a lower triangular matrix. An incomplete Cholesky factorization is given by a sparse lower triangular matrix K that is in some sense close to L . The corresponding preconditioner is KK^* .

One popular way to find such a matrix K is to use the algorithm for finding the exact Cholesky decomposition, except that any entry is set to zero if the corresponding entry in A is also zero. This gives an incomplete Cholesky factorization which is as sparse as the matrix A .

Algorithm

For i from 1 to N :

$$L_{ii} = \left(a_{ii} - \sum_{k=1}^{i-1} L_{ik}^2 \right)^{\frac{1}{2}}$$

For j from $i + 1$ to N :

$$L_{ji} = \frac{1}{L_{ii}} \left(a_{ji} - \sum_{k=1}^{i-1} L_{ik} L_{jk} \right)$$

Implementation

Implementation of the incomplete Cholesky factorization in the Octave scripting language. The factorization is stored as a lower triangular matrix, with the elements in the upper triangle set to zero.

```
function a = ichol(a)
    n = size(a,1);

    for k=1:n
        a(k,k) = sqrt(a(k,k));
        for i=(k+1):n
            if (a(i,k) != 0)
                a(i,k) = a(i,k)/a(k,k);
            endif
        endfor
        for j=(k+1):n
            for i=j:n
                if (a(i,j) != 0)
                    a(i,j) = a(i,j) - a(i,k)*a(j,k);
                endif
            endfor
        endfor
    endfor

    for i=1:n
        for j=i+1:n
            a(i,j) = 0;
        endfor
    endfor
```

```
endfor  
endfunction
```
